

The ICPC Contest Data Server (CDS)

An ICPC Tool

Introduction

The Contest Data Server (CDS) is a software component designed to allow secure, authenticated HTTP connections to contest data residing on a contest network. It provides [REST](#) entry points for accessing a variety of contest-related services, allowing clients to access those services via standard HTTP requests.

The CDS provides authentication services using configuration data supplied by the Contest Administrator (CA). Authenticated users can be assigned *roles* by the CA; user access to specific services is governed by the role(s) assigned to them.

The set of services made available by the CDS is dependent on the facilities available on the contest network. Examples of services which the CDS knows how to support (assuming that the contest network provides the back-end data required and that the CA configures their use into the CDS) include

- an overview description of the contest (title, date, etc.)
- a Countdown Clock for the start of the contest
- the current contest time (time remaining in the contest)
- the contest configuration, as defined by any of several standard file types (contest.yaml, problemset.yaml, teams.tsv, etc.)
- the current backup copy of any specified team's home directory
- the event feed as provided by the Contest Control System (CCS)
- images for each team and for each team's University Logo
- "reaction videos" showing a team's web camera at the moment they received a run submission response from the judges
- the current contest scoreboard
- an RSS feed for the contest
- the set of files which a team submitted to the judges for a specific run

Many of these services are described in more detail in the following sections of this document; additional information regarding CDS services can be found on the [\[CLI Contest Data Package specification\]](#)

Note: many of the data access functions provided by the CDS require the use of a compatible *Contest Control System* (CCS) for running the contest. See the *Competitive Learning Institute's* [Contest Control System specification](#) for details. See the documentation for the CCS being used by your contest to determine whether it meets the CLI CCS specification.

Using the CDS

Overview

The CDS is a Java Enterprise Edition (JavaEE) web application; an instance of the CDS operates by being deployed on a JavaEE application server. The ICPC Tools distribution of the CDS comes pre-packaged running on [Open Liberty](#); the entire CDS can be run using the embedded Liberty server without any other tools.

Alternatively, the CDS can be deployed on other Application Servers such as [Apache Tomcat](#), [JBoss](#) (now [WildFly](#)), or [Jetty](#). However, the mechanisms and requirements for deploying web applications to application servers differ between servers. This guide does not attempt to provide tutorial details for such alternative deployments; see the Appendices and the documentation for your particular application server for additional information.

Installing the CDS

To install the CDS, download a copy of the latest version from the [ICPCTools website](#) and unzip it into any convenient directory. That's it!

Configuring the CDS

The unzipped CDS contains a single folder named *wlp* (Liberty). Among the subfolders therein you will find both *bin* and *usr* folders. The *bin* folder contains commands (see below) which are used to start and control the server and the applications it contains (in this case, the CDS). The *wlp/usr/servers/cds* folder holds the “WAR” file which contains the CDS executable code (under the *apps* folder), and also holds the *configuration files* which manage the CDS configuration.

The CDS is configured via a combination of two things: the JavaEE application server-specific configuration mechanism (for ports, virtual hosts, users, etc.), and XML configuration files for CDS settings (such as which Contest Control System (CCS) to connect to, user account passwords, etc.).

Configuring the WLP JavaEE Server

The Liberty configuration is managed by a file named *server.xml* located in the *usr/servers/cds* folder. The *server.xml* file contains five important sections:

- a specification of the *HTTP and HTTPS ports* used by the server.
 - The ports associated with HTTP and HTTPS requests can be changed by editing the *httpEndpoint* entry in the *server.xml* file; the defaults are 8080 and 8443 respectively.
- a list of the *security roles* and *user names* associated with those roles.
 - The security roles and associated user names can likewise be edited (but be aware that some ICPCTools assume that certain users are associated with certain roles). See below for further information about user roles.
- the location of the *users.xml* file which defines the passwords for user accounts.
 - The passwords assigned to specified user names can be changed by editing the *users.xml* file.
- a **JNDI** (Java Naming and Directory Interface) entry giving the path from which to load the CDS configuration details.
 - The *server.xml* configuration file must contain a single JNDI entry named “icpc.cds.config” that gives the path to load the CDS configuration and other files required by the CDS. The CDS comes preconfigured with a JNDI entry pointing to the current folder, which contains the file *cdsConfig.xml* (see below).
- a list of *features* used by the JavaEE server (not normally changed by CDS users).

Configuring CDS User Roles

The *server.xml* file by default defines four *security roles* and several *user names* occupying those roles, as follows:

Role	Purpose	Default User Names
admin	Super user	admin
blue	Read-only access to all data	blue
balloon	World Finals specific	balloon
trusted	Data accessible to trusted tools	myicpc, live
public	Data accessible to anyone	public, presentation

The user names can be changed to anything you wish and can be added or removed, but must remain in an appropriate “CDS role”. The CDS verifies that authenticated users have the appropriate role before granting access to a specific CDS service. (The “blue” role name comes from the ICPC World Finals network configuration, where core components occupy a network segment called the “Blue Network”; the names “live”,

“myicpc”, and “presentation” refer to groups or functions at the World Finals.)

The Contest Administrator can add, delete, or change the roles and/or the user names defined in the *server.xml* file – but as noted above, be aware that some ICPCTools rely on a user being part of a specific role.

Configuring CDS Services

In addition to the general configuration items described above, the CDS must be made aware what specific services are available on the contest network as well as how it should access those services in order to expose them to clients. This configuration is done via an XML file named *cdsConfig.xml*, located in the *usr/servers/cds* folder. The *cdsConfig.xml* file contains a root element *cds* which in turn contains a separate “service-defining” XML element for each service which the CDS knows how to provide. All nested elements and attributes are optional except for the *contest location* attribute, and unknown elements or attributes are ignored - this allows you to easily rename or comment-out an element to add or remove a service. If you save changes to *cdsConfig.xml* while the CDS is running the changes will be automatically applied after a few seconds.

A simple example of a *cdsConfig.xml* file is shown below.

```
<!-- specify the location of the folder holding the contest data package
      (used to find config files, resources, etc.) -->
<contest location="/Users/me/contests/test" recordReactions="true">
  <!-- Configure communication with the CCS -->
  <ccs url="http://myccs/api/contests/finals" user="admin" password="admin"/>
</contest>
</cds>
```

The above file specifies two “service elements”: *contest*, with its (required) *location* attribute which points to the location of the Contest Data Package (see below), and *ccs*, whose attributes describe how to connect to the Contest Control System. (See below for further description of the attribute values in the sample file.)

CDS Configuration Service Elements

The CDS supports a variety of service-defining XML elements in the *cdsConfig.xml* file. The supported service-defining elements and their structure and functions are described below.

contest Element

```
<contest id="id" location="path" recordReactions="false"/>
```

The optional *id* attribute specifies the contest id to expose, which will override any contest id used by the underlying CCS or event feed. If unspecified, the id will be picked up from the CCS’ Contest API endpoint (e.g. ‘finals’ in ‘http://api/contests/finals’) or by the last segment of the location (e.g. ‘test’ in ‘C:\icpc\test’).

The *location* attribute specifies the full path to a contest data package (CDP) defining the organization of the contest (config files, logos, etc.). See the [CLI CDP specification](#) for details on how to organize a Contest Data Package. Note that *the location attribute is required*; the CDS will not operate if it does not have a folder to store contest related data, even when it is empty and getting all data from the CCS.

**** recordReactions:** an optional string (“true” or “false” [default]) instructing the CDS whether or not to record reaction videos and make them available through the contest API. + If the value of this attribute is “true”, then clients will be able to access reaction videos (60-second snippets following the moment a team sent a submission to the judges). The value of the *recordReactions* attribute should only be set “true” if the *webcam* URL template has been set and team machines are actively streaming webcam video.

The optional *hidden* attribute specifies that a contest should be hidden from contest listings unless the request is coming from an admin or blue user. This allows contest administrators to configure the next contest prior to broadcasting it’s existence. Note that this is just meant to allow some configuration to happen in private, not a way to completely secure these contests.

ccs Child Element

```
<ccs
  url=""
  user=""
  password=""/>
```

The optional *ccs* element is used to configure the CDS's access to the Contest Control System. The attributes associated with this element are as follows:

- url: the URL to a REST-based CCS
- user: the user account name to log into the CCS
- password: the password for the CCS user account

If the *ccs* element is present then the CDS will use the CCS as the master source of all contest data. The local *contest* folder is used as an initial source, cache, and can provide additional data (e.g. logos if the CCS does not provide those) but the event feed and all other contest data will come from or be overridden by the CCS.

ccs Child Element (deprecated)

```
<ccs
  eventFeed=""
  startTime=""
  user=""
  password=""/>
```

Only one *ccs* element may be used. This alternate and deprecated *ccs* element is provided to connect to older CCSs that do not support the CLI Contest API. It provides support for the final [XML Event Feed specification](#) and [Contest Start Interface](#). The attributes associated with this element are as follows:

- eventFeed: (host:port) the IP address and port at which the CDS should contact the CCS to obtain its event feed
- startTime: the optional URL at which the CDS should contact the CCS to obtain the scheduled start time of the contest. The return start time is expected to be in mSec since the start of the Unix epoch (i.e., since midnight January 1st, 1970)
- user: the optional user account name to log into the CCS Start Interface
- password: the optional password for the CCS Start Interface user account

video Child Element

```
<video
  id="43"
  desktop="http://..."
  desktopMode="lazy"
  webcam="http://..."
  webcamMode="eager"
  audio="http://..."
  audioMode="eager"/>
```

The *video* element is used if your contest supports team desktop (screen), webcam, and/or audio streaming, in which case the CDS can make these streams available to clients. Also, if the contest does support team webcam streaming, then the CDS can be instructed to record “reaction videos”, which are 60-second snippets of webcam video started at the moment a team submits a run to be judged (which, assuming the automated judging result is returned to the team within 60 seconds, will have the effect of capturing the team’s “reaction” when they receive the judgment).

The attributes associated with the *video* element are as follows:

- **id**: an optional team id. If this is specified, the video URLs below will be configured only for the given team. If not specified then the video URLs will be configured for all teams.
- **desktop**: an optional template for the URL at which the CDS should access team desktop streams. The URL template may include the characters `{0}`, which will be replaced with the team id by the CDS. For example, if each team machine was on a single /24 subnet (i.e., the first three octets of the team machine IP addresses were all the same) and further the last octet of each team machine's IP address was the team number, then a *desktop* attribute of the form `http://a.b.c.{0}:9090` would direct the CDS to access each team's desktop at port 9090 on the machine with IP address a.b.c.X, where 'X' was the team id (typically team number). As another example, *webcam* URL templates of the form `http://host/{0}` or `http://host:{0}` would direct the CDS to access each team's webcam at a different web-based context root or port, respectively. Note that the URL template mechanism works the same for the *desktop*, *webcam*, and *audio* attributes. In any case, it is the responsibility of the Contest Administrator to ensure that each team machine is actively outputting desktop video, webcam video, and/or audio streams at the specified URL. (See the Appendices for information on setting up video streaming for team machines.) In order to support easy testing, the desktop attribute may also point to a local file instead of a URL, e.g. `c:/desktop_sample.m2ts`. Desktop and webcam files for testing should be roughly 1 min in length as they're streamed every 60s.
- **desktopMode**: an optional string ("lazy", "lazy close", or "eager") that tells the CDS how to access the desktop stream. "Lazy" will connect only when the first client requests the stream and disconnect when the last client drops. "Lazy close" will only connect when a client requests the stream but will stay connected afterward, thus allowing any subsequent clients to connect faster. "Eager" will connect immediately and stay connected even when there are no clients - using up lots of resources, but allowing clients to always connect as fast as possible.
- **webcam**: an optional template for the URL at which the CDS should access team webcam streams. The URL template may include the characters `{0}`, which will be replaced with the team id by the CDS. See the desktop attribute for further details.
- **webcamMode**: an optional string ("lazy", "lazy close", or "eager") that tells the CDS how to access the webcam stream. See the desktopMode attribute for further details.
- **audio**: an optional template for the URL at which the CDS should access team audio streams. The URL template may include the characters `{0}`, which will be replaced with the team id by the CDS. See the desktop attribute for further details.
- **audioMode**: an optional string ("lazy", "lazy close", or "eager") that tells the CDS how to access the audio stream. See the desktopMode attribute for further details.

test Child Element

```
<test
  countdown=""
  startTime=""
  multiplier=""/>
```

The *test* element is used to enable test (*contest playback*) mode. When you enable test mode the CDS will attempt to play back a past contest based on the content of the specified *contest location* (see the *contest* element, above) – meaning, the CDS will provide responses to service requests as if the requested data came from the specified contest, at the time rate and sequence order in which they actually occurred in that contest. The attributes associated with this element are as follows:

- **countdown**: a string giving the number of seconds before the contest playback should start
- **startTime**: a specific start time, e.g. "2018-02-19T12:30:00.000-05"
- **multiplier**: a string giving a numeric multiplication factor for contest time; for example, "50.0" will playback a 5-hour (300-minute) contest in 6 minutes.

Only one of the countdown and startTime attributes can be set at a time! Several services normally require

additional hardware or software to run; e.g. `/video/desktop` requires a team machine that's capturing and streaming desktop video. To avoid this requirement during a test (contest playback), the CDS allows you to put into the contest location (CDP) a *test* folder that contains some sample data. The following is a list of the sample files that are supported:

- `reaction.m2ts`
- `submission.json`
- `backup.tar.gz`

video Element

```
<video
  name="ICPC Live"
  url="http://..."
  mode="lazy"/>
```

The global *video* element is used if you want to add additional video streams into the channel mixer.

The attributes associated with this *video* element are as follows:

- `name`: an name to represent this video stream
- `url`: a video URL at which the CDS can access a video stream
- `mode`: an optional string ("lazy", "lazy close", or "eager") that tells the CDS how to access the desktop stream. "Lazy" will connect only when the first client requests the stream and disconnect when the last client drops. "Lazy close" will only connect when a client requests the stream but will stay connected afterward, thus allowing any subsequent clients to connect faster. "Eager" will connect immediately and stay connected even when there are no clients - using up lots of resources, but allowing all clients to connect as fast as possible.

domain Element

```
<domain>
  <user name="presAdmin"/>
  <user name="presentation1"/>
  <user name="presentation2"/>
</domain>
```

The global *domain* element is used if you have multiple presentation administrators and clients and want to set up separate administrative domains. You can define multiple domains. Each domain should have at least one admin or presentation admin user, and at least one non-admin user that will be used to display presentations.

By defining a domain you are restricting a set of administrators who may control a given set of user's presentations. For example, the domain above means that only `presAdmin` may control `presentation1` and `presentation2` - other administrators will not see these clients unless there are other domains defined. For more complex scenarios domains can overlap in any way, e.g. the primary admin may be included in more than one domain or presentation users may be in multiple domains to allow more than one admin to control them.

The attribute associated with the *user* element is as follows:

- `name`: the name of a user, which must match one of the existing users.

teamUser Element

```
<teamUser>
  <user name="team1" teamId="1"/>
  <user name="steven" teamId="2" host="steven.com"/>
  <user name="mark" teamId="2" host="10.0.0.2"/>
</teamUser>
```

The global *teamUser* element allows you to map a team user login to their identity (team id) within a contest. By providing this mapping the team will be able to see all of their own judgements and clarifications in the contest. In the example above, there is one login for the team with id 1, and two logins for team 2.

If your users are on a locked-down network with known host names or IP addresses, you can add a host attribute to enable auto-login. When this is specified any user from the given host will be automatically logged into the CDS. In order for this feature to work, you must be using basic authentication with the users.xml in the default location (in order for the CDS to look up passwords).

The attribute associated with the *user* element is as follows:

- name: the name of a user, which must match one of the existing users.
- teamId: the team's id within a contest.
- host: an optional host to use for auto-login.

Starting the CDS

The CDS distribution includes a folder *bin* (under the *wlp* folder) that contains a variety of scripts and other tools for performing CDS-related functions. Among these scripts are a Bourne shell script named *server*, and a corresponding Windows batch file named *server.bat*. These are the scripts that are used to start the WLP application server on the corresponding platform. (Note that this structure allows the same command, “*server*”, to be used regardless of the platform.)

The “*server*” script requires one or more parameters telling the WLP application server what to do. In particular, the following table shows the most common commands for running the CDS on the WLP Application Server (the listed commands assume the user is in the *wlp* folder and are shown in their Linux form; replace the “/” characters with “\” on a Windows machine).

Command	Effect
/bin/server start cds	Start the CDS in background mode (allows running other commands from the same prompt, but discards server console output)
/bin/server stop cds	Stop the CDS
/bin/server run cds	Start the CDS in foreground mode (ties up the console window, but allows display of server output)
/bin/server status cds	Displays the current status of the CDS
/bin/server list	List the servers which WLP knows about

Accessing CDS Services

Once the CDS is configured and started, it provides REST entry points (URLs) which clients can access to obtain services. The full form of a URL is always

```
<protocol>://<host>:<port>/<contextRoot>/<pathWithinApp>
```

The CDS defaults to using HTTP and HTTPS protocols at ports 8080 and 8443 respectively (although the port is configurable, as described earlier), and the default *contextRoot* for the CDS (that is, the place where the application server expects to find application pages) is “/”, so a typical URL for accessing CDS services is

```
https://<host>:8443/<serviceName>
```

where *host* is the IP address of (or a hostname which resolves to the IP address of) your CDS machine, and *serviceName* is the name of one of the services provided by the CDS.

For example, assuming the CDS is running on a machine with hostname “*cds*” under the application server’s “/” context root (the default), a client could access the “overview” service by referencing the following URL:

```
https://cds/overview
```

Similarly, accessing

`https://cds/images/team/3`

would return the picture for team #3, and accessing

`http://cds/video/camera/17`

would connect to the video camera stream for team #17. (Note that all of the above examples presume that the corresponding service has been configured into the CDS, as described earlier.)

A complete list of the services provided by the CDS can be found on the [Contest Data Server](#) web page.

Updating ICPC Clients

When using any of the ICPC Tools clients (presentations, balloon printer, coach view, and resolver) with the CDS, they will check the CDS for newer versions on startup, and will automatically download and replace themselves if a newer version is available. To use this function, download the zip file of a newer version of a tool and place it in the CDS's config/present folder.

For example, if a balloon client had the 2.2.87 version installed and you downloaded the 2.2.90 version and placed it at `wlp/usr/servers/cds/config/present/balloonUtil-2.2.90.zip`, the next time the balloon client is started or restarted it will update to 2.2.90. The presentation admin can be used to force a restart of any client.

Appendix

Setting up Video Streaming on Team machines

In order for the CDS to be able to respond to video service requests (for example, access to team machine desktop or team webcams), two things must be done. First, the CDS must be configured to look for team desktop and/or webcam feeds (see the description of the *video* service element in the *cdsConfig.xml* file, above). Second, the Contest Administrator must arrange for team machines to generate appropriate video streams on the URLs which are specified in the *video* element.

Any mechanism can be used to generate the video streams on the team machines. At the World Finals, the free open-source package called [VLC](#) is used. Specifically, each team machine has VLC installed, and two instances of VLC are running on each team machine: one to generate the team desktop stream, and a second to generate the team webcam stream. The commands used to generate these streams are shown below.

Note that while this works at the World Finals, it is possible you will have to do some tweaking to get it to work in your environment. In particular, for example, the commands contain references to specific image resolutions. In addition, note that the commands are run using Linux “sudo” at the World Finals. That is, the actual command used is

```
exec /usr/bin/sudo -u camera -H vlc_command > /dev/null 2>&1 &
```

where *vlc_command* represents the VLC command shown below.

In any case, the commands shown below will hopefully be enough to point you in the proper direction.

Team WebCam Streaming

The following single-line command is used at the World Finals to start a stream on port 8080 containing the team's web camera output:

```
vlc -I dummy -q v4l2:///dev/video0:width=1280:height=720:aspect-ratio="16:9"  
:input-slave=alsa://plughw:1,0 --sout '#transcode{venc=x264{keyint=15},vcodec=h264,  
vb=0,scale=0,fps=30,acodec=mpga,ab=128,channels=2}:http{mux=ts,dst=:8080}'
```

Team Desktop Streaming

The following VLC command is used at the World Finals to start a stream on port 9090 showing the team's screen:

```
vlc -I dummy -q screen:// --screen-fps=30 --sout  
"#transcode{venc=x264{keyint=15},vcodec=h264,vb=0}:http{mux=ts,dst=:9090/}"
```

Deployment Under Other Application Servers

The CDS distribution comes packaged with an embedded Liberty application server. The CDS application component of this distribution is contained in the file *CDS.war* in the *wlp/usr/servers/cds/apps* folder.

In principle it should be relatively easy to “port” the CDS to a different application server by installing the *CDS.war* file in the new application server according to that server’s rules (along with configuring the new application server in ways analogous to the settings described earlier in this document – for example, specifying the location of the *cdsConfig* file to the new application server).

However, as of this writing we have not explicitly attempted such a port. We would be very interested in hearing about user experiences in porting the CDS to other application servers, especially common servers such as *Tomcat*, *Jetty*, or *JBoss/WildFly*.

If you have any experience in attempting such a port, please feel free to update us about it by sending mail to icpctools-dev@ecs.csus.edu.
